# **Executive Summary**

The past 10 years have seen major changes in what were thought to be truisms about toxic chemicals and human health—that there was a clear dose level below which health effects would not occur and that the U.S. population as a whole had been exposed to few toxic chemicals. Scientists are now finding that toxic chemicals impact health at much lower levels than previously believed. Research has also documented widespread exposure to various chemicals through measuring the levels in human blood, urine, and tissue. These changes have come from improvements in measurement techniques enabling researchers to detect extremely low concentrations of chemicals, often several orders of magnitude lower than just a few years ago.

Exposure is more widespread than previously thought, and some chemicals induce health effects at extremely low dose levels. These concerns have led to an emerging consensus that the incidence of chronic ailments and developmental disabilities is connected in some way to toxic chemical exposures. The incidence of some illnesses potentially linked to chemical exposure is increasing. How does exposure to toxic chemicals occur? We know that as a result of regulation and public disclosure, emissions of toxic chemicals to the environment—at least those emissions we track—are declining, so people's potential exposure from those sources should be declining as well.

Previous analyses of data from New Jersey and Massachusetts, the two states that track quan tities of toxic chemicals, show that amounts shipped as or in products are much greater than the amounts of chemicals released to the environment. This is not surprising, since several industries in those states are in the business of producing toxic chemicals.

Much of that "product," however, also becomes raw material for other facilities that manu facture products likely to be used in the home. *Cabinet Confidential* examines amounts of chemicals shipped in products from those facilities and focuses on specific chemicals that are known or suspected neurotoxins, carcinogens, or reproductive or developmental toxins. Certainly, most consumers would expect that products in their homes will contain minimal amounts of these particular chemicals. While New Jersey and Massachusetts may not be rep resentative of the U.S. as a whole, the results show that environmental releases of these types of chemicals are small compared to the tens of millions of pounds of these chemicals shipped in products from facilities in those states. Among the findings:

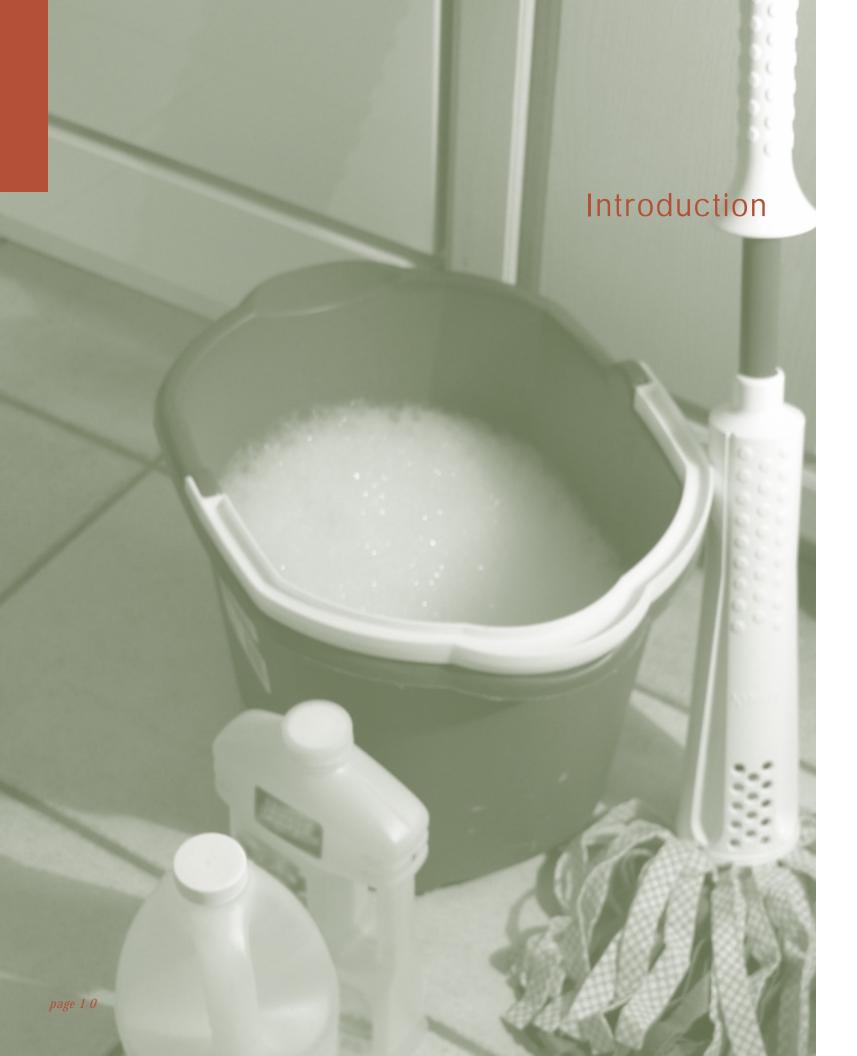

- On average, for every pound of neurotoxins, carcinogens, or reproductive or developmental toxins facilities in New Jersey and Massachusetts report as released to the air, water, or land, they ship 42 pounds of the same chemicals as or in products that could be used in or around the home.
- The top 10 chemicals shipped as or in products examined for this report are all neurotoxins. In addition, one of the 10, toluene, is a developmental toxin, and lead compounds and creosote are carcinogens.
- The top five chemicals shipped as or in products that are likely to be inhaled by users are chlorine, toluene, xylene, methyl ethyl ketone, and n-hexane.
- The five industry categories that shipped the most neurotoxins, carcinogens, or reproductive or developmental toxins in products are paints, varnishes, and enamels; specialty cleaning products; motor vehicle and passenger car bodies; adhesives and sealants; and wood preservatives. These five industrial classifications account for more than 85 percent of the amount of the chemicals examined in this report.

• While most of the amount of chemicals shipped as or in products was intended to be part of the product, a substantial portion was not, such as raw material impurities, solvents, or unreacted chemicals. Together, these represent millions of pounds of toxic chemicals "along for the ride," serving no particular purpose in the product.

Cabinet Confidential calls on policymakers to consider a number of reforms to address the problem of toxics in products:

- Congress should require nationwide reporting of chemicals in products as is currently required in Massachusetts and New Jersey. As in those two states, the tracking can be combined with programs that have explicit goals for reducing the use of toxic chemicals.
- Virtually all of the chemicals examined in this report were "grandfathered" under the Toxic Substances Control Act of 1976 (TSCA), meaning that they are exempt from even the rudimentary requirements of the Act. Since 1976, Congress has broken new ground in reducing pesticide exposures through the Food Quality Protection Act, and the European Union is considering a wide-ranging program that will dramatically change its regulation of toxic chemicals. Congress should apply lessons from these policies and revise TSCA. Specifically, TSCA should require industry to identify the potential health effects of exposure to chemicals that are used in products and accelerate the introduction of less toxic or non-toxic alternatives.
- In the meantime, the other federal agencies with some jurisdiction over products—primarily the Food and Drug Administration and the Consumer Product Safety Commission—should reform the way they deal with issues of chemical exposure to reflect recent science on low-level exposures and a precautionary ethic.
- To help gauge the extent of potential exposure, the Centers for Disease Control should expand its bio-monitoring program to include chemicals found in products used in and around the home.

page 8 page 9

The last 10 years have seen an explosion of science exploring the links between toxic chemicals and human health. The science tends to reinforce some major themes: (1) health effects are often seen at very low levels of exposure—several orders of magnitude lower than previously thought; (2) human exposure to many industrial chemicals is widespread; and (3) increased incidence of various chronic diseases may be linked to toxic exposures.

The landmark environmental laws of the 1970s have succeeded in reducing the toxic pollution of the air, land, and water that is a byproduct of manufacturing. These laws have largely failed, however, to deal with the use of chemicals in the products themselves. *Cabinet Confidential* shines a light on the chemicals that are put in manufactured products and suggests ways that national policies can be updated to address this source of exposure.

### **Emerging Consensus: People are More Vulnerable to Toxic Chemicals**

Peer-reviewed studies in scientific journals such as *Environmental Health Perspectives* continuously find that common chemicals impact health at lower levels than previously believed. Chemicals as ubiquitous as lead,¹ cadmium,² bisphenyl-A,³ and phthalates⁴ have all been found to cause profound health effects at very low levels in recent years. In the case of lead, researchers could only discover the lower level effects after bans on lead in paint and gaso line succeeded in reducing the levels in a majority of children.

There has also been increased attention to the fact that in the real world—as opposed to the laboratory—people are exposed to multiple chemicals at the same time. Some chemicals have similar mechanisms of toxicity and therefore their effect on the body is additive. (Two small doses of each may be the same thing to the body as getting a larger dose of one.) Combinations of other chemicals are believed to be synergistic—producing different effects together than they would separately.

In the early '90s, a panel of the National Academy of Sciences (NAS) declared that children were more vulnerable to toxic chemicals than adults and that policies governing pesticide exposures failed to protect them. Congress reacted to the panel's findings and incorporated them into the Food Quality Protection Act of 1996. The FQPA reformed the way EPA sets the allowable amounts of pesticide residues left on food to reflect children's special vulner ability and cumulative exposure. Though the NAS report focused specifically on pesticides, the same principles apply to other chemical uses. Yet the NAS report has not prompted a similar reform in the area of industrial and commercial chemicals.

### Toxic Chemicals and Chronic Diseases

Various chronic diseases have increased in incidence during the last two decades, prompting some experts and policy makers to call for more comprehensive tracking of diseases and environmental exposures to toxic chemicals. According to the Trust for America's Health:

- The number of people with asthma increased 75% between 1980 and 1994. Among children under four, the disease has exploded by 160%. Today, asthma attacks are the number one cause of school absenteeism.
- Endocrine and metabolic chronic diseases like diabetes increased 20% between 1986 and 1995.
- The number of low birth weight and premature babies has been rising since 1980, and birth defects are the number one killer of infants in America today.
- Neurological diseases such as multiple sclerosis increased 20% between 1986 and 1995.
- Brain cancers and other tumors in children's nervous systems rose by more than 25% between 1973 and 1996.
- Leukemia, the most common childhood cancer, increased more than 15% over the past 20 years. 6

The federal government currently monitors a cross-section of the population for exposure to toxic chemicals, but has yet to link that information with information tracking various diseases. In February 2003, the Centers for Disease Control (CDC) documented that a broad sample of Americans carry over 100 chemicals in their blood and urine.<sup>7</sup> The chemicals include those deliberately added to products, like phthalates, as well as some that are in the

environment as a by-product of combustion, like dioxin. Studies by other governments and private entities have similarly documented widespread human exposure to common indus trial chemicals all over the world. Senator Hillary Clinton (D–NY) and Representative Nancy Pelosi (D–CA) have called for a national program to coordinate and improve disease tracking and match it with the CDC data on chemical exposures.

Even without a national system to track environmental exposures and diseases, scientists already attribute environmental exposure to chemicals to disease incidence. A June 2000 NAS panel estimated that 25% of developmental and neurological deficits in children were due to the interplay between these chemicals and genetic factors and that 3% were caused by exposure to the chemicals alone. Recent studies have confirmed earlier research demonstrat ing a link between home pesticide use and leukemia rates in children. An exhaustive study of twins published in the *New England Journal of Medicine* in 2000 concluded that environ mental factors—including toxic chemicals—play the principal role in causing cancer com pared with heredity. 10

### **Examining Chemicals in Products**

Against the backdrop of scientific concern about the links between exposure to toxic chem icals and human health effects, it is odd that chemicals in products have received relatively little scrutiny. This is due, in part, to the fact that the main law governing chemicals (besides pesticides) in products—the Toxic Substances Control Act (TSCA)—has proved to be a paper tiger when compared to environmental laws such as the Clean Air Act and Clean Water Act. There is no approval process for chemicals in products that is comparable to the one the FDA oversees for drugs. Using data from New Jersey and Massachusetts, *Cabinet Confidential* suggests that this oversight responsibility is significant, because the amount of chemicals going into consumer products dwarfs the amount that is released as waste into the air, land, and water. In addition, the data show that millions of pounds of chemicals are shipped in products that appear to have no function in the products—amounts that otherwise would not be accounted for in environmental reporting.

page 1 2 page 1 3

Data reported under programs for New Jersey and Massachusetts between 1995 and 2000 show that more than one billion pounds of over 100 chemicals known or suspected to be neurotoxins, carcinogens, or reproductive or developmental toxins were included in products shipped from certain manufacturing facilities in those states. These facilities in 53 different industrial classifications produce products that are likely found in the home, although some products from individual facilities may also be intended for industrial or manufacturing purposes. Table 1 lists the top 25 such chemicals shipped by these industries for 1995-2000. Table 2 lists the top industrial classifications by amounts of chemicals shipped as or in products, and Table 3 lists the top industry/chemical combinations. A full version of each of the tables appears in Appendix I. Appendix II contains the methodology and assumptions used in developing this report.

In reviewing these data, it is important to keep the following limitations and qualifications in mind:

- The presence of chemicals in products potentially found in the home does not necessarily mean that people are directly exposed to all, or even some, of these chemicals during use of particular products. This report does not attempt to estimate exposure levels or risk.
- Having said that, however, this report does make a distinction between volatile chemicals—those more likely to vaporize—because they could potentially be inhaled, and non-volatile chemicals, for which exposure would occur through ingestion (oral exposure) or through the skin (dermal exposure). Obviously, people using these products can take precautions

to minimize inhalation exposure, but this is generally more difficult than avoiding swallowing or touching the products. In addition, inhalation is often a more significant exposure route than oral or dermal exposure.

- Because this report examines industrial classifications and not specific products made at individual facilities, it is not possible to say that an individual product will contain a given toxic chemical. For example, although the paints, varnishes, lacquers, enamels, and allied products industry (SIC code 2851) as a group reported shipping toluene as or in products, it does not mean that every product from each facility in SIC code 2851 contains toluene.
- Although this report contains data submitted by industrial classifications selected for producing products likely to be found in and around the home, facilities do not report the amount of chemicals shipped in products actually intended for home use. There are no data available to determine exactly how much of the amount of chemicals shipped in products actually end up in products intended for home use.
- The data used in this report were those collected by New Jersey and Massachusetts, and they are subject to the rules of those reporting programs. The programs do not include every chemical that could be classified as a neurotoxin, carcinogen, or reproductive or developmental toxin that may be shipped in products intended for use in the home. Facilities reporting the data used in this report are not required to measure the amounts of these chemicals shipped as or in products, but only to provide good-faith estimates from available data.

Finally, while these results only apply to facilities in New Jersey and Massachusetts making it impossible to extrapolate for the U.S. as a whole, there is no reason to assume these two states have higher concentrations of toxic chemicals in products than the other 48. In fact, New Jersey and Massachusetts are the only ones to establish specific programs to reduce the use of toxic chemicals by industry.

### The Consumer Product Safety Commission and Vinyl Toys

Soft toys made from polyvinylchloride (PVC) plastic contain di-isononyl phthalate (DINP), a chemical that makes hard plastic more pliable and that is known to damage the liver and kidneys. When children put soft PVC toys in their mouths, they swallow DINP that leaches from the plastic.

In November 1998, the National Environmental Trust and 11 other environmental and public health organizations petitioned the Consumer Product Safety Commission (CPSC) to remove DINP from all toys intended for children up to age five. They also asked for a national health advisory on these products. After extensive press coverage, CPSC and U.S. toy manufacturers voluntarily agreed in December 1998 to remove DINP from toys intended for the mouth while CPSC studied potential risk to children from soft PVC toys.

CPSC completed its review in 2002 and found that that DINP is more toxic than previously thought. A CPSC advisory panel lowered the maximum amount of DINP that could be consumed without potential health effects by 20 percent, despite chemical industry requests to raise the level.11 With this new acceptable daily intake and measurements of the amount of DINP that leaches from PVC, CPSC concluded that children could mouth soft PVC toys safely up to 75 minutes a day. CPSC then commissioned a study to observe children's mouthing behavior, and determined that children spend less than 75 minutes a day mouthing soft PVC toys. This led CPSC to conclude that DINP in PVC toys posed no health risk to children. While the mouthing study was large and seemingly comprehensive, it failed to account for the fact that soft PVC toys were much less available at the time it was conducted due to the manufacturers' voluntary agreement with CPSC to remove PVC toys from the market. With fewer of these products available, children would necessarily spend less time with them in their mouths than before the ban. Relying on this flawed logic, CPSC decided that soft PVC toys were safe, and declined to make the ban mandatory-a move that would have encompassed imports and "down-market" retail outlets. The refusal to formally ban DINP from vinyl toys removes the leverage that convinced domestic toy makers to agree to the voluntary withdrawal in the first place. In fact, soft vinyl toys may be more available in the

In contrast, the European Union (EU) issued an emergency ban on soft PVC teething toys on December 1, 1999, and its decision has been reaffirmed repeatedly since. Japan issued a similar ban in 2002 on DINP in toys that might be mouthed by children under six. Once again, the CPSC was unmoved by the science that prompted action by our major trading partners to protect public health, nor were the various findings translated into public health protection in the United States.

### Top Chemicals

The top 10 chemicals shipped as or in products examined for this report are all neurotoxins. In addition, toluene is a developmental toxin, and lead compounds and creosote are carcinogens. (See Table 1. Appendix I, Table 1 lists the particular known or suspected health effects for each of the chemicals.)

The top five chemicals shipped as or in products that are likely to be inhaled by users of these products are chlorine, toluene, xylene, methyl ethyl ketone, and n-hexane. Together, they account for nearly half of the amount of chemicals shipped in products analyzed by this report.

### **Top Industrial Classifications**

The five industries that shipped the most neurotoxins, carcinogens, or reproductive or devel opmental toxins in products are paints, varnishes, and enamels (SIC 2851); specialty cleaning products (2842); motor vehicle and passenger car bodies (3711); adhesives and sealants (2891); and wood preservatives (2491). (See Table 2.) These five industrial classifications account for more than 85 percent of the amounts of the chemicals examined in this report that were shipped as or in products.

### **Industry/Chemical Combinations**

Table 3 lists the top industry/chemical combinations for amounts of neurotoxins, carcino gens, and reproductive or developmental toxins shipped in products between 1995 and 2000. While chlorine in specialty cleaning products tops the list, the paints, varnishes, and enamels industry accounts for 10 of these 25 top combinations. Lead compounds shipped in motor vehicle and automobile bodies is number two on the list, and accounts for almost 12 percent of all the chemicals examined in this report that were shipped in products between 1995 and 2000. While people are unlikely to be directly exposed to the lead or ethylene glycol contained in auto bodies, they may be exposed to other substances such as toluene and n-hexane also reported as shipped in products by this industry.

### Amount Shipped in Products Not Intended to Be in the Product

Most of the chemicals shipped as or in products are intended to be part of the product, such as formulation components. However, some chemicals become part of products because they are present as impurities in raw materials or because they are created as by-products during manufacture. They could also be materials that were used in processing, such as solvents or catalysts, or they could be reactants that were not completely consumed or removed. No matter what the reason, they represent an unintended potential source of exposure.

Surprisingly, large amounts of neurotoxins, carcinogens, and reproductive or developmental toxins are simply "along for the ride" in a variety of products likely to be found in the home. Overall, over 10 million pounds of these chemicals shipped as or in products are not supposed to be there. For individual chemicals and industries, however, the percentages are much higher. For example, 92 percent of these chemicals shipped in products by fabric finishers and 47 percent of these chemicals shipped in non-rubberized coated fabrics are not intended to be part of the actual product (*see* Table 2). Similarly, thirty-two percent of the ethylene glycol shipped in adhesives and sealants is not intended to be there (*see* Appendix I, Table 3).

page 2 0 page 2 1

### Releases to the Environment per Pound of Intended Use in Product

These data show that, on average, for every pound of neurotoxins, carcinogens, or reproductive or developmental toxins facilities report as released to the air, water, or land, manufacturers ship 42 pounds of these chemicals as or in products. And the 42 pounds is just an average. For some industry/chemical combinations, the ratio is much higher. For example, for neuro toxic glycol ethers in soaps and detergents, the ratio is 1,800 to one. For some volatile organic chemicals in paints and adhesives, the ratio is in the hundreds.

Obviously, facilities are in the business of producing products and not releases to the environment, so it is not surprising that more chemicals end up in products than in air, water, or land. Still, these data are important because of the large numbers and the scarcity of such information except for New Jersey and Massachusetts. Releases to the environment are reported nationally and sometimes regulated under state and federal programs. Amounts shipped as or in products are only reported in two states, and regulation is far more elusive. While it is well beyond the scope of this report to compare the relative risk from living near a facility that produces paint to painting the average home, the large ratio of amounts in products to releases suggests that the products represent potentially important sources of exposure.

### The U.S. Food and Drug Administration and Bisphenyl-A

The U.S. Food and Drug Administration (FDA) regulates levels of additives and contaminants in food sold in the United States. In general, the agency puts the burden of proof on industry to show that additives are safe before approving their use in food. The FDA's policy for unintentional or environmental contaminants is less clear-cut: its action levels and tolerances for unintentional contaminants are based partly on health considerations and partly on the potential market impacts of its decisions and regulations. For substances that will find their way into food during preparation, storage, or serving, however, FDA policy is even less transparent. Such is the case with plastics containing bisphenyl-A (BpA).

BpA was originally developed in the early twentieth century and has been known to act like a hormone in the human body since the 1930's. Polymerized into polycarbonate plastic, it is used in thousands of clear plastic products including baby bottles. Not all the BpA gets polymerized. Some can migrate or leach from polycarbonate plastic, and peer-reviewed studies have documented health effects in the offspring of animals exposed to Bp-A at and below concentrations of parts per billion.

A 1997 FDA study found that BpA migrates out of polycarbonate baby bottles into liquid inside the bottles when they are heated.<sup>12</sup> This result was confirmed by *Consumer Reports*.<sup>13</sup> A Japanese university study also found that BpA migrated from polycarbonate containers, including baby bottles, at even lower temperatures than FDA studied, again resulting in food concentrations of BpA in the parts-per-billion range.<sup>14</sup> In Japan, the finding prompted a swift change in the Japanese school lunch program that provided hot soup in polycarbonate bowls.

Despite these actions, FDA declined a 1999 petition from a coalition of public interest groups asking the agency to investigate BpA's effects. The agency also refused the petition's request to identify the range of food containing products that would likely contain or become contaminated with BpA or similar chemicals and to require them to meet a standard of safety.<sup>15</sup>

The FDA's inaction continues in the face of new evidence that low-levels of BpA are harmful. Most recently researchers were able to trace a stunning increase in the equivalent of Downs Syndrome in a population of laboratory rats when a new cleaning procedure for the animals' polycarbonate water bottles greatly increased the concentration of BpA in their drinking water.<sup>16</sup>

The landmark environmental laws of the 1970s have succeeded in reducing the end-of-the-pipe pollution that results from industrial activities. The recent Toxics Release Inventory (July 2003) showed a continuation of the trend toward declining levels of emissions to air, land, and water for the facilities required to report. Unfortunately, as *Cabinet Confidential* shows, smokestack and pipe emissions are only part of the problem, contributing on average just one pound of pollution for every 42 pounds of chemicals put into the manufactured goods themselves.

These products have a life cycle all their own from the factory, to the home or office, and then finally as waste. During this cycle they can expose consumers, workers, and the environment to many of the same chemicals that our pollution laws have targeted. At the same time, new studies increasingly link chemicals to diseases and other health effects, often at very low levels of exposure. The Centers for Disease Control continues to document widespread exposure to commercial chemicals by examining blood and tissue samples from a broad cross section of Americans.<sup>17</sup> Still, federal policy has largely ignored the issue of chemicals in products, even as the laws governing pesticides and drinking water have been updated to reflect new scientific findings.

The emerging understanding of health effects from common commercial chemicals, combined with our increased awareness of the sources and extent of exposure to them, demands an urgent reexamination of federal policy. Key questions include: What chemicals are in this product? Are they safe? What alternatives exist? These questions must move from the periphery to the center of federal environmen tal policy making, just as they have in Europe and in several states.

### Tracking Chemicals in Products

As the "Methodology" section in Appendix II makes clear, this report was only possible because of policies in Massachusetts and New Jersey requiring facilities to report chemical use. These states are alone in requiring manufacturers to distinguish between the chemicals they use, generate, and put in products from the amounts they emit into the environment, and to document both sources of potential exposure.

New Jersey and Massachusetts also have planning programs specifically designed to reduce the use of toxic chemicals "at the source" of manufacturing. The Pollution Prevention Act and the Toxics Use Reduction Act, respectively, require industrial facilities to examine their processes for opportunities to reduce the use or generation of toxic chemicals. Massachusetts also provides technical assistance. The combination of expanded right-to-know and use reduction planning has shown some success, especially in reducing the amount of chemical waste.

Similar "source reduction" laws in California and Oregon have proven less successful, partly because there is no expanded right-to-know requirement to create incentives for taking the planning require ments seriously and to track results. The same is true of the federal Pollution Prevention Act. Combining source reduction planning with chemical use reporting at the state and federal level could yield substantial reductions in the use of toxic chemicals. A federal program to report chemical use should be established to protect the public's right-to-know and to spur corporations' interest in positive public relations that would drive innovations to reduce the use of toxic chemicals in products. These two forces are widely credited by industry and environmentalists with the success of the federal Toxic Release Inventory (TRI) program in reducing toxic pollution.

### Weak Law Leads to Voluntary Measures on Health Effects

Some health effects information is available for most of the chemicals identified in this report. Either federal or California lists, for example, identify certain chemicals as neurotoxins, carcinogens, or reproductive or developmental toxins. For the vast majority of the 70,000 chemicals used in commerce, however, publicly available health effects information is non-existent.

This is partly due to the federal law governing toxics in products, which has turned out to be a paper-tiger (in contrast to the landmark pollution laws). For the chemicals already on the market at the time-of its passage, the Toxic Substances Control Act (TSCA) requires EPA to show that a chemical presents-an "unreasonable risk" and to demonstrate likely human exposure before the EPA can require it to be-

tested. Because the testing is needed to help demonstrate risk, the law has been ineffective with the large group of untested chemicals. TSCA does require pre-manufacture notices for those chemicals intro duced since the passage of the law, and EPA has used this provision to raise questions about some chemicals—prompting industry to withdraw them—and has moved to restrict the use of others. Yet, the majority of chemicals in commerce remain unregulated by this law.

Spurred by an investigation by Environmental Defense, the EPA found that only seven percent of the approximately 3,000 chemicals produced in high volumes (in quantities over one million pounds per year) had a basic set of publicly available toxicity information. The percentage is believed to be worse for the tens of thousands of additional chemicals produced in smaller volumes.

In 1998, the EPA and the American Chemistry Council, with the participation of Environmental Defense, set up the voluntary High Production Volume (HPV) Challenge Program to develop basic health effects information by 2005 for chemicals made or imported in quantities of one million pounds or more per year. Chemicals raising "red flags" in this basic screening would be singled out for compre hensive testing. As of summer 2003, the program's progress was mixed. Commitments to evaluate hundreds of chemicals have been made, but there are approximately 500 "orphaned" chemicals for which industry will not take responsibility and many others for which fundamental toxicological assessments have yet to be done. Thus the program has produced only modest results so far. <sup>19</sup> Work on a similar program, the Voluntary Children's Testing Program, is too preliminary to provide results.

### Consumer Product Safety Commission Fails to Fill the Gap

The U.S. Consumer Product Safety Commission (CPSC) has failed to fill the gap left by environmen tal laws. Technically empowered to ensure product safety, including protection from chronic environ mental hazards in products, the CPSC has often been unwilling or unable to act. By its very nature, the commission is reactive and not preventive. It is designed to respond to evidence of harm in products on the market, rather than to identify hazards or certify products prior to their introduction. CPSC is particularly ill-suited to preventing chronic environmental hazards where the evidence of harm may manifest itself years after exposure to a toxic chemical. The CPSC is also hobbled by protocols requiring it to first work with industry groups to voluntarily withdraw or withhold a product that is harmful before it can order a ban. Compared to the European Union and Japan, the CPSC has been slow, even recalcitrant, to act in the face of science indicating certain products are hazardous. (See the sidebar on vinyl toys on page 17.)

page 2 6

### The Food and Drug Administration and Toxics in Products

The FDA has jurisdiction over certain consumer products that contain toxic chemicals, including food wraps and cosmetics, yet it has failed to use its authority to ensure these products are safe. In November 2002, for example, the FDA's review panel for cosmetics ingredients declined to follow the lead of the European Union and ban carcinogens and reproductive toxins in cosmetics. In 1998, the FDA also failed to respond to new science showing the ubiquitous chemical bisphenol-A, used as a softener for plastic, posed a hazard by leaching from baby bottles, food wraps, and other items containing polycar bonate plastic. (See bisphenol-A sidebar, page 23.)

### **Europe Integrates Health Effects and Chemical Regulation**

Over the last several years, the European Union has moved to rationalize and integrate its regulation of toxic chemicals in ways that provide a model for the United States. The Registration, Evaluation, and Authorization of Chemicals (REACH) policy<sup>20</sup> was formally proposed in May 2003 and is almost sure to be enacted in some form by the EU over the next three years. The registration policy would require industry to generate health effects information for chemicals that have none by a specific deadline. For chemicals produced in very large quantities, or others that raise concerns during the registration phase, the EU member states will evaluate the science and propose possible restrictions. Chemicals already identified as carcinogens, reproductive toxins, mutagens, or Persistent Bioaccumulative Toxins (PBTs)—and others the registration process may reveal—will require authorization on a case-by-case basis in order to continue their use in products or manufacturing. The authorization will look at such real world issues as: Does the manufacturer need to use the chemical in this product? How feasible are alternatives?

Though the REACH proposal may be further modified by the European Parliament, it has set a high bar for policy on industrial and commercial chemicals. Few could argue with the idea that we should know the health effects of chemicals that are used in products or released into the environment. Similarly, it makes sense to minimize or eliminate the use of those chemicals we already know (or later discover) to be harmful. Still, U.S. policy has not explicitly adopted these goals. Instead, we have relied on a mixture of voluntary initiatives like the HPV Challenge and crisis management and intervention when the evidence of harm is overwhelming and acute.

### Products as Waste and Extended Producer Responsibility

Even when products such as discarded computers and other electronic equipment don't expose con sumers to the toxics they contain during their useful life, they may expose other people and the envi ronment when they become waste. Investigators have uncovered the terrible environmental and human health effects of China's sprawling, unregulated computer "recycling" industry. Recycling centers for large appliances and cars have also been hampered by the toxic content of the products they disman tle, and some have contributed to or become Superfund sites. State legislatures and members of Congress are considering plans to regulate the toxic waste of the electronics industry with mechanisms similar to the beverage container deposit systems that exist in several states. At the same time, European and Japanese experience suggests that policies requiring manufacturers to take responsibility for the lifecycle of the product produce better results. Such policies provide an incentive for manufactures to incorporate safety into product design more than policies that place the primary responsibility on the government.

### State Governments' Innovations

State governments have been quicker to respond to the issue of toxic chemicals in products than the federal government. Massachusetts and New Jersey have both tracked chemical use and chemicals shipped as or in products for almost two decades. California voters passed Proposition 65 in 1986, which requires manufacturers using a carcinogen or reproductive toxin to issue a warning prior to exposing the public. This law has led to the reformulation of hundreds of products by manufacturers seeking to avoid printing a warning statement on packaging and has generated much useful informa tion on the health effects of certain chemicals. California's air agencies have also regulated the toxic content of some consumer products because of their contribution to smog and ambient levels of toxic air pollution. In 2003, Governor Gray Davis signed legislation phasing out the use of two of the three most common flame retardants because of evidence that they were accumulating in breast milk of women living throughout the state and because safer alternatives were available. Washington State has adopted a goal of phasing out Persistent and Bio-accumulative Toxins (PBTs) in the state. In each of these cases, the state governments have shown a greater willingness to tackle the problem of toxic chem icals closer to the source than has the federal government.

page 2 8 page 2 9

Products likely to be found in the home may contain far higher amounts of potentially toxic chemi cals—and thus may present a much greater exposure risk—than manufacturers release into the air, water, and soil. The actual quantities of these chemicals and their effects on humans are unknown, making them an unacceptable health risk for Americans. The following policy recommendations are intended to address this issue:

- 1. Congress should enact a national system to track and report chemical use in products, modeled on the programs in New Jersey and Massachusetts.
- 2. Congress should reform the Toxic Substances Control Act so that the EPA can more effectively anticipate and prevent adverse health effects from toxic chemicals in products. The reform should be modeled generally on the European Union's REACH policy and base allowable exposure levels on children's heightened vulnerability to chemicals, similar to the Food Quality Protection Act's standard for pesticides.
- **3.** Congress should continue to fund bio-monitoring and health tracking initiatives at the Centers for Disease Control (CDC) and state health departments to improve our understanding of links between toxics and illness and to help inform enlightened public policy.
- **4.** The CDC should expand its bio-monitoring program where feasible to include chemicals found in products potentially used in the home, such as those identified in this report.
- 5. The CPSC and FDA could vastly improve their performance simply by implementing existing law. The FDA should reverse its decision on toxic chemicale in cosmetics to bring it into line with Europe, and it should end the practice of delegating decisions to an industry-funded panel. Similarly, the CPSC should revisit its decisions to allow the continued use of phthalates in toys despite readily available alternatives.
- **6.** States should continue to innovate and compensate for shortcomings in national chemical policy, as Washington, California, New Jersey, and Massachusetts have done.
- States should devise their own bio-monitoring and health-tracking programs to develop crucial local data and inform regulatory interventions.

### Appendix I: Tables

This appendix contains complete versions of the data tables presented in the "Results and Discussion" section of the report.

### Appendix II: Methodology

### **Data Sources**

This report uses data from a number of sources, all current as of December 2002:

- Data on toxic chemicals from certain facilities in Massachusetts were taken from Toxic Use Reports filed under the Massachusetts Toxic Use Reduction Act (TURA). Data for 1995-2000 were obtained on a CD-ROM disc provided by Massachusetts' Department of Environmental Protection, TURA program. Facilities report these data if they are within certain industries, have more than 10 full-time employees, and use certain toxic chemicals above listed thresholds. The reporting requirements follow those of the federal Toxic Release Inventory (TRI), except that beginning in 1995, Massachusetts required certain non-manufacturing industries to report data, and it also requires chemicals on the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) list to be reported. Massachusetts has also de-listed a few chemicals from TURA reporting that are found on the TRI and CERCLA lists. Reporting criteria for TURA can be found at <a href="https://www.state.ma.us/dep/bwp/dhm/tura/turapubs.htm">www.state.ma.us/dep/bwp/dhm/tura/turapubs.htm</a>.
- Similar data for some facilities in New Jersey were taken from Release and Pollution Prevention Reports (RPPR) filed under the authority of the New Jersey Worker and Community Right-to-Know Act. Data for 1996-1997 were obtained from the New Jersey Department of Environmental Protection (DEP) website, <a href="http://www.state.nj.us/dep/enforcement/relprev/crtk/index.html">http://www.state.nj.us/dep/enforcement/relprev/crtk/index.html</a>; data for 1998-2000 were sent electronically by New Jersey DEP in October 2002. Data for 1995 were obtained from Hampshire Research, a consulting firm which had done additional data quality work for a previous report using these data. Facilities complete RPPR reports only if they also report federal Toxic Release Inventory (TRI) forms; therefore the data are limited to certain industries, to facilities with more than 10 full-time employees, and those that use certain toxic chemicals above thresholds. Reporting criteria for TRI/RPPR can be found at <a href="https://www.epa.gov/tri/">www.epa.gov/tri/</a>.
- Lists of reproductive and developmental toxins, and of carcinogens, were taken from the California Proposition 65 list, <www.oehha.ca.gov/prop65.html>, updated in June 2002.
- A list of known and suspected neurotoxins was obtained from the "Scorecard" website maintained by Environmental Defense, <www.scorecard.org>, updated September 2002.
- Some facilities in the Massachusetts and New Jersey databases had missing SIC code (industrial classification) information; in addition, the Massachusetts database does not collect TRI-style manufacturing, processing, and use codes which were used in this report's analysis. These data were obtained

from the federal TRI in cases where a facility was missing information but could be linked to its record within TRI. TRI data were taken from a copy used by the Right-to-Know Network, RTK NET, <www.rtk.net>.

Chemicals were listed in this report if they were reported to the New Jersey or Massachusetts databases (i.e., if they were on the TRI or CERCLA chemical lists) and if they appeared on the Proposition 65 list of carcinogens, the Proposition 65 list of reproductive or developmental toxins, or the Scorecard list of suspected neurotoxins. A few chemicals were eliminated because they have been de-listed from the federal TRI. The final chemical list used in this report can be found in Appendix I, Table 1.

### Industries That Produce Products Likely to be Found in the Home

Only certain industries are included in this report. Specific industries that make products likely to be found in or around the home were selected from the list of those reported by the two databases. In general, these were foods and household consumer products, although certain other industries (such as car bodies) were added to fully reflect the range of potentially toxic chemicals used in and around the home. Some industries manufacture both consumer and industrial products, and in these cases an ad hoc decision was made to include or exclude the entire industry.

The final list of industries used can be seen in Appendix I, Table 2, along with some sample products produced by each industry. No effort was made to verify that the particular facilities that reported within these industries actually made products that match the sample products listed. The industry was classified based on its primary Standard Industrial Classification (SIC) code as shown on its New Jersey or Massachusetts reporting form. Records with blank SIC codes used SIC information from TRI if a link between the two could be made. Some facilities reported SIC codes that were valid under the 1977 rather than the standard 1987 SIC list; these were converted to the more recent code numbers when possible. Some facilities reported more than one SIC code per form: in these cases the first SIC code was taken to be the primary one as described in reporting instructions.

Although petroleum refineries were not included in this report, those in New Jersey shipped over 100 billion pounds of neurotoxins, carcinogens, and reproductive or developmental toxins in products between 1995 and 2000. While these data dwarf all the other industries profiled in this report, it is unclear how much of the product produced from these facilities was gasoline and how much was industrial lubricants. More perplexing was how much of the chemicals of interest were in each type of product. Even if the amount that was gasoline could be determined, it would be difficult to project the amount of gasoline that would have gone into passenger cars and light trucks versus heavy trucks.

page 4.2 page 4.3

## Data on Releases, Amounts Shipped As or in Products, and Chemical Use

Amounts of toxic chemicals listed in this report consist of releases, amounts reported as shipped as or in products, and total use amounts. Releases are totals of amounts reported released to air, water, land, or underground on-site at each facility; these are reported in similar fashion in the Massachusetts and New Jersey databases, both of which have TRI-style reporting. Amounts of toxic chemicals going into products are reported as simple data fields within both databases. Calculating the total amount of toxic chemical use is somewhat more complicated because these data are reported differently within the two databases, and because it is constructed from other quantities.

- For New Jersey, the amount of chemical used was calculated as the amount in inventory at the start of the year minus the amount in inventory at the end of the year, plus the amount produced, plus the amount brought on-site, plus the amount recycled on-site.
- For Massachusetts, the amount of chemical used was calculated as the sum of the amounts manufactured, processed, and otherwise used.

In cases where the calculated usage amount was less than the total amount released, transferred off-site, and going into products, the usage amount was adjusted upwards to equal this total. For the data used within this report, this resulted in a total upward adjustment of 4.2 million pounds (for a total of 560 million pounds) of chemical use in Massachusetts and 31 million pounds (to make a total of 1.5 billion pounds) for New Jersey. All amounts in this report are in pounds, except for quantities of dioxin and dioxin-like compounds which are reported in grams.

# Chemicals Shipped As or in Products That Are Not Intended to Be in Products

For some data analyses, amounts in products were separated into amounts intended to be in the products (because the chemical is part of the product formulation) and amounts left in the products as contaminants or remnants of the production process. This second category was referred to as "amounts not intended in product." Categorization was done using the manufacturing, processing, and other use codes used in the TRI and the New Jersey database. Facilities in Massachusetts had these codes taken from TRI in cases where a link to a TRI report for the facility could be established. The codes were evaluated as follows:

• If the facility indicated that the chemical was manufactured for sale or distribution, or processed as a formulation component, an article component, or for repackaging, this indicated that some of the chemical was an intended element of the product;

- If the facility indicated that the chemical was manufactured as a by-product or an impurity, processed
  as a reactant or process impurity, or otherwise used as a chemical processing aid, manufacturing aid,
  or for ancillary use, this indicated that some of the chemical was not an intended element of the product;
- If the form had codes indicating that some of a chemical was intended to be in the product and codes showing that some was not, it was impossible to tell how much was intended for the product. In these cases, which account for approximately 25 percent of chemical use, all of the chemical was counted as intended for the product. Only the chemicals with codes showing that they were "not intended in the product" were listed in the not intended category.

It is also possible that some of these unintended amounts shipped as or in products are the result of incorrect reporting by manufacturers. There are two plausible explanations for this. The first is that the amount reported is simply an error. The second is more complicated. Materials accounting programs such as those in New Jersey and Massachusetts have an inherent bias that the chemical inputs and outputs should balance. In other words, the amount of a substance brought on site, plus the amount produced on site, should equal the amount of the substance consumed in processing, added to the amounts shipped as or in product, and the amount generated as waste (including amounts managed as waste on site, released to the environment on site, and shipped off site for management or disposal). Obviously, whether or not the totals balance depends on how each quantity is estimated. In some cases when the inputs and outputs do not balance, facilities may put the "extra" inputs into the shipped as or in product category, particularly when the quantities needed for balance are small.

Another slight discrepancy is that some industries and chemicals will be underrepresented in this report in comparison to others because the reporting criteria have changed from year to year. Quantities in this report are totals of those reported from 1995 through 2000. Changes in reporting requirements will cause totals for chemicals reported in all six years to appear larger than those only reported for one or two years. For instance, certain chemicals, such as dioxin, were either added to the requirements or had their threshold lowered in 2000 when EPA included Persistent Bioaccumulative Toxics in the TRI. Some of these chemicals will therefore have only one year of data included. (Another major change to TRI in 1998—the addition of non-manufacturing industries—does not affect this report, because those industries were not included in the list of ones likely to cause household exposure.) Similarly, some chemicals will be underrepresented in the totals because they were reported either to the Massachusetts or the New Jersey database, but not to both. This includes some CERCLA chemicals, such as sodium phosphate (tribasic), ethyl acetate, sodium hypchlorite, and butyl acetate.
